

Database Management

A **database** is a structured, organized collection of data stored electronically in a computer system. Databases allow users to input, store, organize, manipulate, search (query), and output data efficiently in either a printed or electronic format. Common database applications include *Microsoft Access* and *LibreOffice Base*.

Database Architecture & Hierarchy of Data

Databases organize data into a strict hierarchy, moving from the smallest structural element (a single attribute) to the largest container (the entire relational system).

- **Field:** A single piece of information or a specific characteristic about an object, person, or event. It represents a column in a database table. Examples include VisitorID, Surname, or DateOfBirth.
- **Record:** A complete set of data relating to a single item, person, or entity. A record is made up of multiple fields and represents a horizontal row in a database table.
- **Table:** A collection of related records structured into rows (records) and columns (fields).
- **Relational Database:** A database structure that contains multiple tables linked together by common fields to share information and eliminate data redundancy.

Fundamental Data Types

When a field is created in a database table, it must be assigned a specific data type. This determines what kind of data can be entered into the field and ensures the computer handles and stores it correctly.

Data Type	Description	Practical Examples
Alphanumeric / Text	Accepts letters, numbers, punctuation marks, and symbols. It is also used for numeric strings that do not require mathematical calculations.	Jon, HR12 4QQ (Postcode), 07700900123 (Telephone)
Numeric / Number	Used exclusively for numbers that will be used in mathematical calculations. Can be whole integers or decimals.	15 (Quantity), 1.85 (Height in meters)
Date / Time	Stores calendar dates and specific times. Automatically enforces standard calendar rules.	24/06/2010, 14:30
Currency	Automatically attaches a monetary symbol and fixes decimal places. Used for financial records.	£25.00, \$120.50
Logical / Boolean	A state that can only hold one of two possible mutually exclusive values.	Yes / No, True / False, M / F

Relational Infrastructure & Key Keys

To connect multiple tables together in a relational database, specific key fields must be established to ensure data integrity.

Primary Key

A **Primary Key** is a field (or a combination of fields) that uniquely identifies each individual record in a database table. No two records in the same table can share the exact same primary key value.

- *Examples:* StudentID, NationalInsuranceNumber, ProductID.

Foreign Key

A **Foreign Key** is a field in one table that links to the primary key field in another table. It is the structural mechanism used to establish and enforce a relationship between the two tables.

Types of Relationships

- **One-to-Many Relationship (1:\infty):** The most common relational structure. A single record in Table A can match multiple records in Table B, but a record in Table B can only match one record in Table A.
 - *Example:* One Customer can place many Orders, but each individual order belongs to only one specific customer.

Enforcing Data Integrity: Validation Checks

Validation is an automatic computer check performed by the software when data is entered into a database. Its purpose is to ensure that the data is sensible, reasonable, and valid before it is accepted into storage.

Important Distinction: Validation checks if data *could* be correct (sensible), but it cannot check if data is *actually* correct (accurate). If a user enters a valid but incorrect postcode, validation will accept it.

Standard Validation Types

- **Presence Check:** Ensures that a field cannot be left completely blank during data entry.
 - *Application:* Making a Surname or EmailAddress field mandatory on a registration form.
- **Range Check:** Checks that a numeric or date value falls within a specified upper boundary and lower boundary.
 - *Application:* Ensuring an examination percentage field only accepts values ≥ 0 and ≤ 100 .
- **Length Check:** Verifies that the data entered contains a specific number of

characters, or stays within a strict character limit.

- *Application:* Setting a Gender field to accept a maximum length of 1 character (M or F), or enforcing a fixed length for a password.
- **Type Check:** Verifies that the entered data matches the data type assigned to that field.
 - *Application:* Preventing a user from accidentally typing alphabetical letters like "abc" into a numeric Age field.

Information Retrieval: Queries & Search Logic

A **query** is a search extraction method used to interrogate a database table and display only the records and fields that meet specific, designated search conditions (criteria).

Relational and Logical Operators

Queries use operators to filter records precisely:

- **Relational Operators:** Used to compare values against one another:
 - = (Equal to)
 - < (Less than)
 - > (Greater than)
 - <= (Less than or equal to)
 - >= (Greater than or equal to)
 - <> (Not equal to)
- **Logical Operators:** Used to combine multiple search conditions together:
 - **AND:** Returns records *only* if **all** specified search criteria are simultaneously met.
 - **OR:** Returns records if **at least one** of the specified search criteria is met.
 - **NOT:** Inverts the search criteria to return everything *except* the specified value.

Multi-Field Sorting

Databases allow you to sort query results using single or multiple fields in either **Ascending** order (A to Z, 0 to 9) or **Descending** order (Z to A, 9 to 0). When sorting by multiple fields, the second field is used to break ties if duplicate values exist in the first sorted field.

Input & Output Operations: Forms, Reports, and Mail Merge

Database interactions are divided into operational interfaces designed for clear inputting and structured outputting.

Data Entry Forms

A **Form** is an onscreen user interface designed to simplify the process of inputting, editing, and deleting records in a database table. Instead of typing data directly into a massive grid

table, forms present clear input text boxes, drop-down menus, and radio buttons for a single record at a time, making data entry less prone to human error.

Database Reports

A **Report** is a formatted, structured presentation of data extracted from a database query or table, specifically designed to be printed or distributed electronically. Unlike tables, reports allow you to group related data, format layouts with custom headers and footers, and calculate summary values (such as grand totals or averages).

Mail Merge Documents

A **Mail Merge** is a process that automatically combines a single word-processed template document (such as a customer notification letter or email) with a structured database table or query address list.

- **Placeholders / Merge Fields:** Special markers (e.g., <<FirstName>>, <<Surname>>) are inserted into the document template.
- When the mail merge is run, the software automatically loops through the database table, replacing the placeholders with unique data values from each record to generate personalized individual letters.

Student Activities

Activity 1: Conceptualizing the Hierarchy of Data

1. Look at the data table provided below:

VisitorID	FirstName	Surname	Gender	Age
1	Jon	Smith	M	24
2	Sarah	Jones	F	31
3	Amanda	Patel	F	19

1. Using the data table above, identify and write down:
 - The total number of **fields** present in this table structure.
 - The total number of data **records** saved into this table.
 - A suitable, data-safe primary key field.

Activity 2: Designing Validation Strategies

Imagine you are setting up a database table to store details for a school's sports club enrollment. For each of the fields listed below, determine the most suitable **Data Type** and select a highly appropriate **Validation Check** that should be implemented to prevent incorrect data entries:

1. StudentID (e.g., STU12345)
2. DateJoined
3. EmergencyContactPhoneNumber
4. PaidMembershipFee (Yes/No status)

Chapter Questions

1. Which database component is represented by a vertical column containing a single type of information across an entire table?
 - A) Record
 - B) Field
 - C) Primary Key
 - D) Relationship
2. Explain why a telephone number or a postal area code must be configured as an Alphanumeric/Text data type instead of a Numeric data type.
3. Describe the distinct roles of a Primary Key and a Foreign Key in establishing a secure link between two database tables.
4. Which one of these validation checks is specifically designed to prevent a critical field on an online database form from being left blank by a user?
 - A) Range Check
 - B) Length Check
 - C) Type Check
 - D) Presence Check
5. A theme park database query needs to extract a list of all visitors who are female (F) AND are aged 18 or older. Write out the logical search criteria statement required to execute this query.
6. Explain the operational difference between running an automated validation check on a database field versus manually proofreading the entered data.
7. State the name of the database feature that is specifically designed to provide an organized, visually polished output layout of query results suitable for printing.
8. State the type of relationship created when a single record in a Customers table can link to multiple separate records in an Orders table.
9. Define what an automated "Mail Merge" process achieves and describe the role that database placeholders play within it.
10. Which relational operator represents the mathematical concept of "Not equal to" within a database query environment?
 - A) <=
 - B) >=
 - C) <>
 - D) ==
